The INDEX is used to create and retrieve data from the database very quickly. Index can be created by using single or group of columns in a table. When index is created it is assigned a ROWID for each rows before it sort out the data.

Proper indexes are good for performance in large databases but you need to be careful while creating index. Selection of fields depends on what you are using in your SQL queries.

## Example:

For example, the following SQL creates a new table called CUSTOMERS and adds five columns:

```
CREATE TABLE CUSTOMERS (
  ID      INT             NOT NULL,
  NAME    VARCHAR (20)    NOT NULL,
  AGE     INT             NOT NULL,
  ADDRESS CHAR (25) ,
  SALARY  DECIMAL (18, 2),
  PRIMARY KEY (ID)
);
```

Now you can create index on single or multiple columns using the folloiwng syntax:

```
CREATE INDEX index_name
  ON table_name ( column1, column2.....);
```

To create an INDEX on AGE column, to optimize the search on customers for a particular age, following is the SQL syntax:

```
CREATE INDEX idx_age
  ON CUSTOMERS ( AGE );
```

## DROP a INDEX Constraint:

To drop a INDEX constraint, use the following SQL:

```
ALTER TABLE CUSTOMERS
  DROP INDEX idx_age;
```
